# Threshold Models for $2 \times 2$ Uncertainty-Certainty Matrices <br> Richard Fiene PhD <br> Research Institute for Key Indicators/Penn State University 

December 2023

This abstract will provide the SPSS outputs for the phi coefficients in utilizing various threshold models for the $2 \times 2$ Uncertainty-Certainty Matrices for determining key indicators. It is intended for regulatory scientists and licensing researchers who will be more interested in this statistical presentation. It follows the two previous RIKINotes posts on the UCM Matrix and the graphic representation of the theory of regulatory compliance, key Indicators, and risk assessments. In fact, these three posts should be read together to get the full understanding of this modeling technique.

The abstract presents three threshold models: $25 / 50 / 25,10 / 80 / 10$, and $5 / 90 / 5$. These models are utilized to determine the high and low regulatory compliance groups that will be used to sort and select the respective key indicators for a jurisdiction's set of rules/regulations. These models are based upon the dichotomization statistical technique which is utilized given the nature of the regulatory compliance data being so severely skewed in a positive fashion towards full compliance with all rules.

It will be noticed in all the models that the key indicators do not change, they are stable which is not surprising since licensing key indicators do not change a great deal over time nor across jurisdictions. The original 13 key indicators that were identified in 2002 in the ASPE publication Thirteen Health and Safety Key Indicators has not changed a great deal over the past two decades. What does change is the significance of the phi coefficients in becoming more statistically significant as we increase the dichotomization of the model in moving from 25/50/25 --> 5/90/5 threshold models in order to eliminate false negatives and decrease false positives. However, with that said, there are limits to this dichotomization in which in some cases phi coefficients may drop off because of the cell sizes in the $2 \times 2$ UCM Matrix becoming smaller.

The threshold models are included as three attachments to this abstract with the phi coefficients for each rule. These data are taken from a western US state but they clearly represent what is found in any jurisdiction when doing this type of analysis related to the threshold models.
